Do's and Don'ts of the Workshop

TODO

Document Structure

We have provided you with an electronic copy of the workshop's hands-on tutorial documents. We have done this for two reasons: 1) you will have something to take away with you at the end of the workshop, and 2) you can save time (mis)typing commands on the command line by using copy-and-paste.

While you could fly through the hands-on sessions doing copy-and-paste you will learn more if you take the time, saved from not having to type all those commands, to understand what each command is doing!

The commands to enter at a terminal look something like this:

```
tophat --solexa-quals -g 2 --library-type fr-unstranded -j \
    annotation/Danio_rerio.Zv9.66.spliceSites -o tophat/ZV9_2cells \
    genome/ZV9 data/2cells_1.fastq data/2cells_2.fastq
```

The following icons are used in the margin, throughout the documentation to help you locate:

- Important
- For reference
- Follow these steps
- Questions to answer
- Warning STOP and read
- Bonus exercise for fast learners
- Advanced exercise for super-fast learners

Resources Used

We have provided you with an environment which contains all the tools and data you will need and use during this workshop. However, we have tried to include at the start of each module, details about the tools and data used.

Module: Data Quality

Primary Author(s): Sonika Tyagi sonika.tyagi@agrf.org.au

Contributor(s):

Nathan S. Watson-Haigh nathan.watson-haigh@awri.com.au

Key Learning Outcomes

After completing this practical the trainee should be able to:

- Assess the overall quality of NGS sequence reads
- Visualise the quality, and other associated matrices, of reads to decide on filters and cutoffs for cleaning up data ready for downstream analysis
- Clean up and pre-process the sequences data for further analysis

Introduction Data Quality

Introduction

Going on a blind date with your read set? For a better understanding of the consequences please check the data quality!

For the purpose of this tutorial we are focusing only on Illumina sequencing which uses 'sequence by synthesis' technology in a highly parallel fashion. Although Illumina high throughput sequencing provides highly accurate sequence data, several sequence artefacts, including base calling errors and small insertions/deletions, poor quality reads and primer/adapter contamination are quite common in the high throughput sequencing data. The primary errors are substitution errors. The error rates can vary from 0.5-2.0% with errors mainly rising in frequency at the 3' ends of reads.

One way to investigate sequence data quality is to visualize the quality scores and other metrics in a compact manner to get an idea about the quality of a read data set. Read data sets can be improved by post processing in different ways like trimming off low quality bases, cleaning up any sequencing adapters and removing PCR duplicates. We can also look at other statistics such as, sequence length distribution, base composition, sequence complexity, presence of ambiguous bases etc. to assess the overall quality of the data set. Highly redundant coverage (>15X) of the genome can be used to correct sequencing errors in the reads before assembly and errors. Various k-mer based error correction methods exist but are beyond the scope of this tutorial.

Prepare the Environment

To investigate sequence data quality we will demonstrate tools called FastQC and fastx-toolkit. FastQC will process and present the reports in a visual manner. Based on the results, the sequence data can be processed using the fastx-toolkit. We will use one data set in this practical, which can be found in the QC directory on your desktop.

Open the Terminal and go to the directory where the data are stored:

- 1 cd ~/QC/
- 2 nwd

At any time, help can be displayed for 'fastqc' using the following command:

1 fastqc -h

Quality Visualisation

We have a file for a good quality and bad quality statistics. FastQC generates results in the form of a zipped and unzipped directory for each input file.

Execute the following command on the two files:

```
fastqc -f fastq bad_example.fastq
fastqc -f fastq good_example.fastq
```

View the FastQC report file of the dab data using a web browser such as firefox.

```
firefox bad_example_fastqc/fastqc_report.html &
```

The report file will have a Basic Statistics table and various graphs and tables for different quality statistics. E.g.:

Table 1: FastQC Basic Statistics table

| Filename | bad_example.fastq |
|--------------------|-------------------------|
| File type | Conventional base calls |
| Encoding | Sanger / Illumina 1.9 |
| Total Sequences | 40000 |
| Filtered Sequences | 0 |
| Sequence length | 100 |
| %GC | 48 |

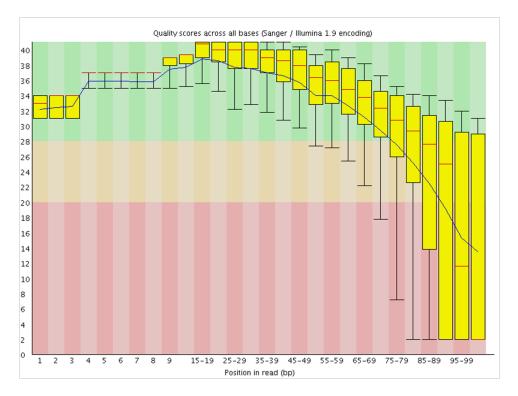

Figure 1: Per base sequence quality plot for bad_example.fastq. Base positions in the reads are shown on x-axis and quality score (Q Score) are shown on the Y-axis

A quality score (or Q-score) expresses an error probability. In particular, it serves as a convenient and compact way to communicate very small error probabilities. Given an assertion, A, the probability that A is not true, P(A), is expressed by a quality score, Q(A), according to the relationship:

$$Q(A) = -10log10(P(\sim A))$$

Where P(A) is the estimated probability of an assertion A being wrong. The relationship between the quality score and error probability is demonstrated with the following table:

Table 2: Error probabilities associated with various quality (Q) values

| Quality score, Q(A) | Error probability, $P(\sim A)$ |
|---------------------|--------------------------------|
| 10 | 0.1 |
| 20 | 0.01 |
| 30 | 0.001 |
| 40 | 0.0001 |

How many sequences were there in your file? What is the read length?

Does the quality score values vary throughout the read length? (hint: look at the 'per base sequence quality plot')

What is the quality score range you see?

At around which position do the scores start falling below Q20?

How can we trim the reads to filter out the low quality data?

Good Quality Data

View the FastQC report files fastqc_report.html to see examples of a good quality data and compare the quality plot with that of the bad_example_fastqc.

firefox good_example_fastqc/fastqc_report.html &

Sequencing errors can complicate the downstream analysis, which normally requires that reads be aligned to each other (for genome assembly) or to a reference genome (for detection of mutations). Sequence reads containing errors may lead to ambiguous paths in the assembly or improper gaps. In variant analysis projects sequence reads are aligned against the reference genome. The errors in the reads may lead to more mismatches than expected from mutations alone. But if these errors can be removed or corrected, the read

Read Trimming Data Quality

alignments and hence the variant detection will improve. The assemblies will also improve after pre-processing the reads with errors.

Read Trimming

Read trimming can be done in a variety of different ways. Choose a method which best suits your data. Here we are giving examples of fixed-length trimming and quality-based trimming.

Fixed Length Trimming

Low quality read ends can be trimmed using a fixed-length timmer. We will use the fastx_trimmer from the fastx-toolkit. Usage message to find out various options you can use with this tool. Type fastx_trimmer -h at anytime to display help.

We will no do fixed-length trimming of the bad_example.fastq file using the following command.

```
cd ~/QC
fastx_trimmer -h
fastx_trimmer -Q 33 -f 1 -l 80 -i bad_example.fastq -o \
bad_example_trimmed01.fastq
```

We used the following options in the command above:

- -Q 33 Indicates the input quality scores are Phred+33 encoded
 - **-f** First base to be retianed in the output
 - -1 Last base to be retained in the output
 - -i Input fastq file name
 - -o Output file name

Run fastge on the trimmed file and visualise the quality scores of the trimmed file.

```
fastqc -f fastq bad_example_trimmed01.fastq
firefox bad_example_trimmed01_fastqc_report.html &
```

The output should look like:

Data Quality Read Trimming

Table 3: FastQC Basic Statistics table

| Filename | $bad_example_trimmed 01. fastq$ |
|--------------------|-----------------------------------|
| File type | Conventional base calls |
| Encoding | Sanger / Illumina 1.9 |
| Total Sequences | 40000 |
| Filtered Sequences | 0 |
| Sequence length | 80 |
| %GC | 48 |

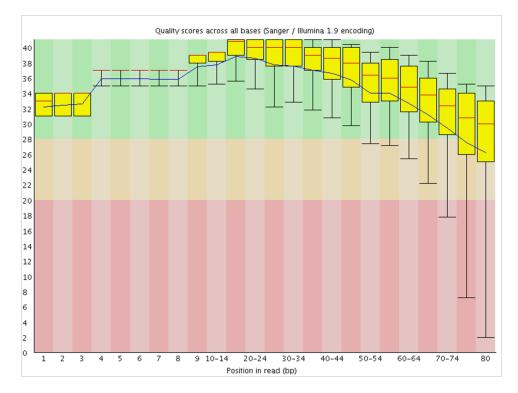

Figure 2: Per base sequence quality plot for the fixed-length trimmed bad_example.fastq reads. Base positions in the reads are shown on x-axis and quality score (Q Score) are shown on the Y-axis

What values would you use for $\neg f$ if you wanted to trim off 10 bases at the 5' end of the reads?

Read Trimming Data Quality

Quality Based Trimming

Base call quality scores can also be used to dynamically determine the trim points for each read. A quality score threshold and minimum read length following trimming can be used to remove low quality data.

11

Run the following command to quality trim your data:

```
cd ~/QC
fastq_quality_trimmer -h
fastq_quality_trimmer -Q 33 -t 20 -l 50 -i bad_example.fastq -o \
bad_example_quality_trimmed.fastq
```

11

Run FastQC on the quality trimmed file and visualise the quality scores.

```
fastqc -f fastq bad_example_quality_trimmed.fastq
firefox bad_example_quality_trimmed_fastqc/fastqc_report.html &
```

The output should look like:

Table 4: FastQC Basic Statistics table

| Filename | $bad_example_quality_trimmed.fastq$ |
|--------------------|--|
| File type | Conventional base calls |
| Encoding | Sanger / Illumina 1.9 |
| Total Sequences | 38976 |
| Filtered Sequences | 0 |
| Sequence length | 50-100 |
| %GC | 48 |

Data Quality Read Trimming

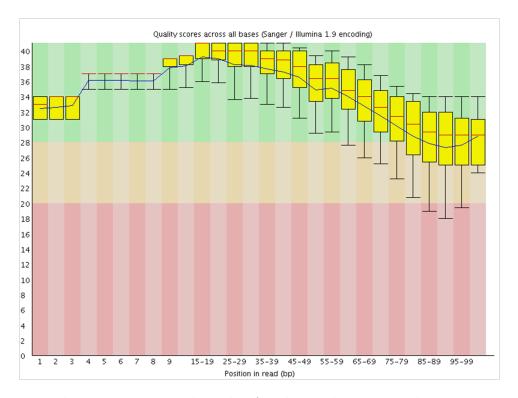

Figure 3: Per base sequence quality plot for the quality-trimmed bad_example.fastq reads. Base positions in the reads are shown on x-axis and quality score (Q Score) are shown on the Y-axis

How did the quality score range change with two types of trimming?

Did the number of total reads change after two types of trimming?

What reads lengths were obtained after quality based trimming?

Did you observe adapter sequences in the data?

Read Trimming Data Quality

Adapter Clipping

Sometime sequence reads may end up getting the leftover of adapters and primers used in the sequencing process. It's good practice to screen your data for these possible contaminations for more sensitive alignment and assembly based analysis. This is particularly important when read lengths can be longer than the molecules being sequenced. For example when sequencing miRNAs.

Various QC tools are available to screen and/or clip these adapter/primer sequences from your data. (e.g. FastQC, fastx, cutadapt).

Here we are demonstrating fastx_clipper to trim a given adapter sequence.

```
11
```

```
cd ~/QC
fastx_clipper -h
fastx_clipper -v -Q 33 -l 20 -M 15 -a \
GATCGGAAGAGCGGTTCAGCAGGAATGCCGAG -i bad_example.fastq -o \
bad_example_clipped.fastq
```

An alternative tool, not installed on this system, for adapter clipping is fastq-mcf. A list of adapters is provided in a text file. For more information, see Fastqmcf at the URL provided at the start of this module.

Removing Duplicates

Duplicate reads are the ones having the same start and end coordinates. This may be the result of technical duplication (too many PCR cycles), or over-sequencing (very high fold coverage). It is very important to put the duplication level in context of your experiment. For example, duplication level in targeted or re-sequencing projects may mean something different in RNA-seq experiments. In RNA-seq experiments oversequencing is usually necessary when detecting low abundance transcripts.

The duplication level computed by FastQC is based on sequence identity at the end of reads. Another tool, Picard, determines duplicates based on identical start and end positions in SAM/BAM alignment files.

We will not cover Picard but provide the following for your information. Picard is a suite of tools for performing many common tasks with SAM/BAM format files. For more information see the Picard website and information about the various command-line tools available:

http://picard.sourceforge.net/command-line-overview.shtml

Picard 1.69 is installed on this system in /usr/share/java/picard-1.69/ One of the Picard tools (MarkDuplicates) can be used to analyse and remove duplicates from the raw sequence data. The input for Picard is a sorted alignment file in BAM format. Short read aligners such as, bowtie, BWA and tophat can be used to align FASTQ files against a reference genome to generate SAM/BAM alignment format. Data Quality Read Trimming

Interested users can use the following general command to run the MarkDuplicates tool at their leisure and only need to provide a BAM file for INPUT:

```
cd ~/QC
java -jar /usr/share/java/picard/MarkDuplicates.jar \
INPUT=<alignment_file.bam> VALIDATION_STRINGENCY=LENIENT \
OUTPUT=alignment_file.dup METRICS_FILE=alignment_file.matric \
ASSUME_SORTED=true REMOVE_DUPLICATES=true
```

Module: Read Alignment

Introduction Read Alignment

Introduction

Prepare the Environment

- We will use one data set in this practical, which can be found in the ChIP-seq directory on your desktop.
- Open the Terminal.
 First, go to the right folder, where the data are stored.
 - 1 cd ~/ChIP-seq
- The .fastq file that we will align is called Oct4.fastq. This file is based on Oct4 ChIP-seq data published by Chen et al. (2008). For the sake of time, we will align these reads to a single mouse chromosome.

Alignment

- You already know that there are a number of competing tools for short read alignment, each with its own set of strengths, weaknesses, and caveats. Here we will try *Bowtie*, a widely used ultrafast, memory efficient short read aligner.
- Bowtie has a number of parameters in order to perform the alignment. To view them all type
 - bowtie --help

Bowtie uses indexed genome for the alignment in order to keep its memory footprint small. Because of time constraints we will build the index only for one chromosome of the mouse genome. For this we need the chromosome sequence in FASTA format. This is stored in a file named mm9, under the subdirectory bowtie_index. The indexed chromosome is generated using the command:

bowtie-build bowtie_index/mm9.fa bowtie_index/mm9

This command will output 6 files that constitute the index. These files that have the prefix mm9 are stored in the bowtie_index subdirectory. To view if they files have been successfully created type:

1 ls -l bowtie_index

Read Alignment Alignment

Now that the genome is indexed we can move on to the actual alignment. The first argument for bowtie is the basename of the index for the genome to be searched; in our case is mm9. We also want to make sure that the output is in SAM format using the -S parameter. The last argument is the name of the FASTQ file.

Align the Oct4 reads using Bowtie:

bowtie bowtie_index/mm9 -S Oct4.fastq > Oct4.sam

The above command outputs the alignment in SAM format and stores them in the file Oct4.sam.

In general before you run *Bowtie*, you have to know which encoding your FASTQ files have. The available FASTQ encodings for bowtie are:

- --phred33-quals Input quals are Phred+33 (default).
- --phred64-quals Input quals are Phred+64 (same as --solexa1.3-quals).
 - --solexa-quals Input quals are from GA Pipeline ver. < 1.3.
- --solexa1.3-quals Input quals are from GA Pipeline ver. ≥ 1.3 .
 - --integer-quals Qualities are given as space-separated integers (not ASCII).

The FASTQ files we are working with are Sanger encoded (Phred+33), which is the default for *Bowtie*.

Bowtie will take 2-3 minutes to align the file. This is fast compared to other aligners which sacrifice some speed to obtain higher sensitivity.

Look at SAM format by typing:

head -n 10 Oct4.sam

Can you distinguish between the header of the SAM format and the actual alignments?

What kind of information does the header provide?

To which chromosome are the reads mapped?

Manipulate SAM output

SAM files are rather big and when dealing with a high volume of NGS data, storage space can become an issue. As we have already seen, we can convert SAM to BAM files (their binary equivalent that are not human readable) that occupy much less space.

Convert SAM to BAM using *samtools* and store the output in the file Oct4.bam. You have to instruct *samtools* that the input is in SAM format (-S), the output should be in BAM format (-b) and that you want the output to be stored in the file specified by the -o option:

samtools view -bSo Oct4.bam Oct4.sam

Compute simple stats of the alignment using samtools:

samtools flagstat Oct4.bam

Visualize alignments in IGV

IGV is a stand-alone genome browser. Please check their website (http://www.broadinstitute.org/igv/) for all the formats that IGV can display. For our visualization purposes we will use the BAM and bigWig formats.

When uploading a BAM file into the genome browser, the browser will look for the index of the BAM file in the same folder where the BAM files is. The index file should have the same name as the BAM file and the suffix .bai. Finally, to create the index of a BAM file you need to make sure that the file is sorted according to chromosomal coordinates.

Sort alignments according to chromosome position and store the result in the file with the prefix Oct4.sorted:

samtools sort Oct4.bam Oct4.sorted

Index the sorted file.

samtools index Oct4.sorted.bam

The indexing will create a file called Oct4.sorted.bam.bai. Note that you don't have to specify the name of the index file when running samtools.

Another way to visualize the alignments is to convert the BAM file into a bigWig file. The bigWig format is for display of dense, continuous data and the data will be displayed as a graph. The resulting bigWig files are in an indexed binary format.

The BAM to bigWig conversion takes place in two steps. Firstly, we convert the BAM file into a bedgraph, called Oct4.bedgraph, using the tool genomeCoverageBed from BEDTools:

genomeCoverageBed -bg -ibam Oct4.sorted.bam -g \
bowtie_index/mouse.mm9.genome > Oct4.bedgraph

Then we convert the bedgraph into a binary graph, called Oct4.bw, using the tool bedGraphToBigWig from the *UCSC* tools:

bedGraphToBigWig Oct4.bedgraph bowtie_index/mouse.mm9.genome Oct4.bw

Both of the commands above take as input a file called mouse.mm9.genome that is stored under the subdirectory bowtie_index. These genome files are tab-delimited and describe the size of the chromosomes for the organism of interest. When using the UCSC Genome Browser, Ensembl, or Galaxy, you typically indicate which species/genome build you are working. The way you do this for BEDTools is to create a "genome" file, which simply lists the names of the chromosomes (or scaffolds, etc.) and their size (in basepairs). BEDTools includes pre-defined genome files for human and mouse in the genomes subdirectory included in the BEDTools distribution.

Now we will load the data into the IGV browser for visualization. In order to launch IGV double click on the IGV 2.1 icon on your Desktop. Ignore any warnings and when it opens you have to load the genome of interest.

On the top left of your screen choose from the drop down menu Mus musculus (mm9). Then in order to load the desire files go to:

1 File > Load from File

On the pop up window navigate to Desktop > ChIP-seq folder and select the file Oct4.sorted.bam. Repeat these steps in order to load Oct4.bw as well. Select chr1 from the drop down menu on the top left. Right click on the name of Oct4.bw and choose Maximum under the Windowing Function. Right click again and select Autoscale. In order to see the aligned reads of the BAM file, you need to zoom in to a specific region. For example, look for gene Lemd1 in the search box.

What is the main difference between the visualization of BAM and bigWig files?

Using the + button on the top right zoom in more to see the details of the alignment.

Practice Read Alignment

What do you think the different colors mean?

Practice

In the ChIP-seq folder you will find another .fastq file called gfp.fastq. Follow the above described analysis for this dataset as well.

Module: ChIP-Seq

Primary Author(s):
Remco Loos, EMBL-EBI remco@ebi.ac.uk
Myrto Kostadima kostadim@ebi.ac.uk

Contributor(s): Xi Li sean.li@csiro.au

Key Learning Outcomes

After completing this practical the trainee should be able to:

- Perform simple ChIP-Seq analysis, e.g. the detection of immuno-enriched areas using the chosen peak caller program MACS
- Visualize the peak regions through a genome browser, e.g. Ensembl, and identify the real peak regions
- Perform functional annotation and detect potential binding sites (motif) in the predicted binding regions using motif discovery tool, e.g. MEME.

 $ChIP ext{-}Seq$ Introduction

Introduction

The goal of this hands-on session is to perform some basic tasks in the analysis of ChIP-seq data. In fact, you already performed the first step, alignment of the reads to the genome, in the previous session. We start from the aligned reads and we will find immuno-enriched areas using the peak caller MACS. We will visualize the identified regions in a genome browser and perform functional annotation and motif analysis on the predicted binding regions.

Prepare the Environment

- The material for this practical can be found in the ChIP-seq directory on your desktop. This directory also contains an electronic version of this document, which can be useful to copy and paste commands. Please make sure that this directory also contains the SAM/BAM files you produced during the alignment practical.
- If you didn't have time to align the control file called gfp.fastq during the alignment practical, please do it now.
 Follow the same steps as for the Oct4.fastq file.
- Of course, the same bowtie index can be used, so the index building step can be skipped.
- In ChIP-seq analysis (unlike in other applications such as RNA-seq) we often would like to exclude all reads that map to more than one location in the genome, to avoid false positives. When using Bowtie, this can be done using the -m 1 option, which tells it to report only unique matches (See bowtie --help for more details).
- Open the Terminal and go to the ChIP-seq directory:
 - 1 cd ~/ChIP-seq

Finding enriched areas using MACS

- MACS stands for Model based analysis of ChIP-seq. It was designed for identifying transcription factor binding sites. MACS captures the influence of genome complexity to evaluate the significance of enriched ChIP regions, and improves the spatial resolution of binding sites through combining the information of both sequencing tag position and orientation. MACS can be easily used for ChIP-Seq data alone, or with a control sample to increase specificity.
- Consult the MACS help file to see the options and parameters:
 - 1 macs --help

The input for MACS can be in ELAND, BED, SAM, BAM or BOWTIE formats (you just have to set the --format option).

Options that you will have to use include:

- -t To indicate the input ChIP file.
- -c To indicate the name of the control file.
- --format To change the file format. The default format is bed
 - --name To set the name of the output files.
- --gsize This is the mappable genome size. With the read length we have, 70% of the genome is a fair estimation. Since in this analysis we include only reads from chromosome 1, we will use as gsize 70% of the length of chromosome 1 (197 Mb).
- --tsize To set the read length (look at the fastq files to check the length).
 - --wig To generate signal wig files for viewing in a genome browser. Since this process is time consuming, it is recommended to run MACS first with this flag off, and once you decide on the values of the parameters, run MACS again with this flag on.
 - --diag To generate a saturation table, which gives an indication whether the sequenced reads give a reliable representation of the possible peaks.

Now run macs using the following command:

```
macs -t [Oct4 aligned bam file] -c [gfp aligned bam file] --format=BAM \
--name=Oct4 --gsize=138000000 --tsize=26 --diag --wig
```

Look at the output saturation table (Oct4 diag.xls). To open Excel files, right-click on them, choose Open with and select OpenOffice. Do you think that more sequencing is necessary? Open the Excel peak file and view the peak details. Note that the number of tags (column 6) refers to the number of reads in the whole peak region and not the summit height.

Viewing results with the Ensembl genome browser

It is often instructive to look at your data in a genome browser. Before, we used IGV, a stand-alone browser, which has the advantage of being installed locally and providing fast access. Web-based genome browsers, like Ensembl or the UCSC browser, are slower, but provide more functionality. They do not only allow for more polished and flexible visualisation, but also provide easy access to a wealth of annotations and external data sources. This makes it straightforward to relate your data with information about repeat regions, known genes, epigenetic features or areas of cross-species conservation, to name just a few. As such, they are useful tools for exploratory analysis.

They will allow you to get a 'feel' for the data, as well as detecting abnormalities and problems. Also, exploring the data in such a way may give you ideas for further analyses.

Launch a web bowser and go to the Ensembl website at http://www.ensembl.org/index.html

Choose the genome of interest (that is, mouse) on the left side of the page. Click on the **Manage your data** link on the left, then choose **Attach remote file**.

One option is to browse to the wig file MACS generated (usually under MACS wiggle/treat) and to upload it to Ensembl (option **Upload data**). However, since wig files describing sequencing signal are very big, they would take a long time to upload, and the browsing process will be very slow.

As a better alternative, wig files can be converted to an indexed binary format and put into a web accessible server (http, https, or ftp) instead on the Ensembl server. This makes all the browsing process much faster. Detailed instructions for generating a bigWig from a wig type file can be found at:

http://genome.ucsc.edu/goldenPath/help/bigWig.html.

We have generated bigWig files in advance for you to upload to the Ensembl browser. They are at the following URL: http://www.ebi.ac.uk/~remco/ChIP-Seq_course/Oct4.bw. To visualise the data:

- Paste the location above in the field File URL.
- Choose data format Bigwig.
- Choose some informative name and in the next window choose the colour of your preference.
- Click **Save** and close the window to return to the genome browser.

Repeat the process for the control sample, located at http://www.ebi.ac.uk/~remco/ChIP-Seq_course/gfp.bw.

After uploading, choose **Configure this page**, and under **Your data** tick both boxes. Closing the window will save these changes.

Go to a region on chromosome 1 (e.g. 1:34823162-35323161), and zoom in and out to view the signal and peak regions. Be aware that the data scale automatically, so bigger-looking peaks need not actually be bigger. Always look at the values on the left hand side axis.

What can you say about the profile of Oct4 peaks?

Compare it with H3K4me3 histone modification wig file we have generated at http://www.ebi.ac.uk/~remco/ChIP-Seq_course/H3K4me3.bw.

Jump to 1:36066594-36079728 for a sample peak. Do you think H3K4me3 peaks regions contain one or more modification sites? What about Oct4?

MACS generates its peak files in a file format called bed file. This is a simple text format containing genomic locations, specified by chromosome, begin and end positions, and some more optional information.

See http://genome.ucsc.edu/FAQ/FAQformat.html#format1 for details. Bed files can also be uploaded to the Ensembl browser.

Try uploading the peak file generated by MACS to Ensembl. Find the first peak in the file (use the head command to view the beginning of the bed file), and see if the peak looks convincing to you.

Annotation: From peaks to biological interpretation

In order to biologically interpret the results of ChIP-seq experiments, it is usually recommended to look at the genes and other annotated elements that are located in proximity to the identified enriched regions. This can be easily done using PeakAnalyzer.

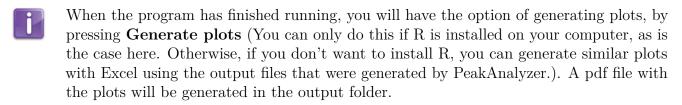

Go to the PeakAnalyzer directory and launch the program by typing:

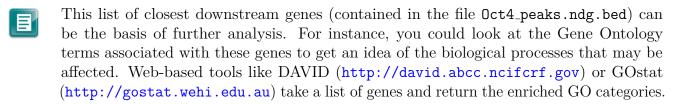

java -jar PeakAnalyzer.jar &

The first window allows you to choose between the split application (which we will try next) and peak annotation. Choose the peak annotation option and click **Next**. We would like to find the closest downstream genes to each peak, and the genes that overlap with the peak region. For that purpose you should choose the **NDG** option and click

ChIP-Seq Motif analysis

Next. Fill in the location of the peak file Oct4 peaks.bed, and choose the mouse GTF as the annotation file. You don't have to define a symbol file since gene symbols are included in the GTF file. Choose the output directory and run the program.

Motif analysis

It is often interesting to find out whether we can associate identified the binding sites with a sequence pattern or motif. We will use MEME for motif analysis. The input for MEME should be a file in fasta format containing the sequences of interest. In our case, these are the sequences of the identified peaks that probably contain Oct4 binding sites. Since many peak-finding tools merge overlapping areas of enrichment, the resulting peaks tend to be much wider than the actual binding sites. Sub-dividing the enriched areas by accurately partitioning enriched loci into a finer-resolution set of individual binding sites, and fetching sequences from the summit region where binding motifs are most likely to appear enhances the quality of the motif analysis. Sub-peak summit sequences can be retrieved directly from the Ensembl database using PeakAnalyzer.

If you have closed the PeakAnalyzer running window, open it again. If it is still open, just go back to the first window.

Choose the split peaks utility and click **Next**. The input consists of files generated by most peak-finding tools: a file containing the chromosome, start and end locations of the enriched regions, and a .wig signal file describing the size and shape of each peak. Fill in the location of both files Oct4 peaks.bed and the wig file generated by MACS, which is under Oct4_MACS_wiggle/treat, check the option to **Fetch subpeak sequences** and click **Next**.

In the next window you have to set some parameters for splitting the peaks.

Separation float - This value determines when a peak will be separated into sub-peaks. This is the ratio between a valley and its neighbouring summit (the lower summit of the two). For example, if you set this height to be 0.5, two sub-peaks will be separated only if the height of the lower summit is twice the height of the valley. Keep the default value. Minimum height - only sub-peaks with at least this number of tags in their summit region will be separated. Set this to be 5. Change the organism name from the default human to mouse and run the program.

Motif analysis ChIP-Seq

Since the program has to read large wig files, it will take a few minutes to run. Once the run is finished, two output files will be produced. The first describes the location of the sub-peaks, and the second is a fasta file containing 300 sequences of length 61 bases, taken from the summit regions of the highest sub-peaks.

Open a web bowser and go to the MEME website at http://meme.ebi.edu.au/meme/cgi-bin/meme.cgi, and fill in the necessary details, such as:

- your e-mail address
- the sub-peaks fasta file Oct4 peaks.bestSubPeaks.fa (will need uploading), or just paste in the sequences.
- the number of motifs we expect to find (1 per sequence)
- the width of the desired motif (between 6 to 20)
- the maximum number of motifs to find (3 by default). For Oct4 one classical motif is known.

You will receive the results by e-mail. This usually doesn't take more than a few minutes.

Open the e-mail and click on the link that leads to the html results page.

Scroll down until you see the first motif logo. We would like to know if this motif is similar to any other known motif. We will use TOMTOM for this. Scroll down until you see the option **Submit this motif to**. Click the TOMTOM button to compare to known motifs in motif databases, and on the new page choose to compare your motif to those in the JASPAR and UniPROBE database.

Which motif was found to be the most similar to your motif?

Introduction RNA-Seq

Introduction

The goal of this hands-on session is to perform some basic tasks in the downstream analysis of RNA-seq data. We will start from RNA-seq data aligned to the zebrafish genome using Tophat.

We will perform transcriptome reconstruction using Cufflinks and we will compare the gene expression between two different conditions in order to identify differentially expressed genes.

Prepare the Environment

We will use a dataset derived from sequencing of mRNA from Danio rerio embryos in two different developmental stages. Sequencing was performed on the Illumina platform and generated 76bp paired-end sequence data using polyA selected RNA. Due to the time constraints of the practical we will only use a subset of the reads.

The data files are contained in the subdirectory called data and are the following:

2cells_1.fastq and 2cells_2.fastq

These files are based on RNA-seq data of a 2-cell zebrafish embryo

6h_1.fastq and 6h_2.fastq

These files are based on RNA-seq data of zebrafish embryos 6h post fertilization

Open the Terminal and go to the directory where the data is stored:

All commands entered into the terminal for this tutorial should be from within the RNA-seq directory above.

Check that the data directory contains the above-mentioned files by typing:

1 ls -l data

RNA-Seq Alignment

Alignment

There are numerous tools performing short read alignment and the choice of aligner should be carefully made according to the analysis goals/requirements. Here we will use Tophat, a widely used ultrafast aligner that performs spliced alignments.

Tophat is based on Bowtie to perform alignments and uses an indexed genome for the alignment to keep its memory footprint small. We have already seen how to index the genome (see Alignment hands-on session), therefore for time purposes we have already generated the index for the zebrafish genome and placed it under the **genome** subdirectory. Tophat has a number of parameters in order to perform the alignment. To view them all type:

11

The general format of the tophat command is:

tophat [options] * <index_base> <reads_1> <reads_2>

Where the last two arguments are the .fastq files of the paired end reads, and the argument before is the basename of the indexed genome.

- Like with Bowtie before you run Tophat, you have to know which quality encoding the fastq formatted reads are in.
- Can you tell which quality encoding our fastq formatted reads are in?
- Look at the first few reads in the file data/2cells_1.fastq and then compare the quality strings with the table found at: http://en.wikipedia.org/wiki/FASTQ_format#Encoding.
 - head -n 20 data/2cells_1.fastq

Some other parameters that we are going to use to run Tophat are listed below:

-g Maximum number of multihits allowed. Short reads are likely to map to more than one locations in the genome even though these reads can have originated from only one of these regions. In RNA-

Alignment RNA-Seq

seq we allow for a restricted number of multihits, and in this case we ask Tophat to report only reads that map at most onto 2 different loci.

--library-type Before performing any type of RNA-seq analysis you need to know a few things about the library preparation. Was it done using a strand-specific protocol or not? If yes, which strand? In our data the protocol was NOT strand specific.

- -J Improve spliced alignment by providing Tophat with annotated splice junctions. Pre-existing genome annotation is an advantage when analysing RNA-seq data. This file contains the coordinates of annotated splice junctions from Ensembl. These are stored under the sub-directory annotation in a file called ZV9.spliceSites.
- -o This specifies in which subdirectory Tophat should save the output files. Given that for every run the name of the output files is the same, we specify different directories for each run.

Since it takes a long time to perform spliced alignments, even for this subset of reads, we have pre-aligned the 2cells data for you using the following command:

DO NOT run this command yourself - you may overwrite the output files of the pre-aligned data.

tophat --solexa-quals -g 2 --library-type fr-unstranded -j \
annotation/Danio_rerio.Zv9.66.spliceSites -o tophat/ZV9_2cells \
genome/ZV9 data/2cells_1.fastq data/2cells_2.fastq

RNA-Seq Alignment

Using the above command as a guide, can you devise and run the command for aligning the 6h data?

The alignment will take approximately 17 minutes. In the meantime please move on with the practical and we will get back to the terminal once the alignment is done

We will firstly look at some of the files produced by Tophat. For this please open the RNA-seq directory which can be found on your Desktop. Click on the tophat subdirectory and then on the directory called ZV9_2cells.

Tophat reports the alignments in a BAM file called accepted_hits.bam. Among others it also creates a junctions.bed files that stores the coordinates of the splice junctions present in your dataset, as these have been extracted from the spliced alignments.

Now we will load the BAM file and the splice junctions onto IGV to visualize the alignments reported by Tophat.

In order to launch IGV type double click on the IGV 2.1 icon on your Desktop. Ignore any warnings and when it opens you have to load the genome of interest.

On the top left of your screen choose from the drop down menu Zebrafish (Zv9). Then in order to load the desire files go to:

File >> Load from File

In the pop-up window, navigate to the Desktop/RNA-seq/tophat/ZV9_2cells directory and select the file accepted_hits.sorted.bam. Once the file is loaded right-click on the name of the track on the left and choose Rename Track. Give the track a meaningful name. Follow the same steps in order to load the junctions.bed file from the same directory. Using the same proceedure, load the Ensembl annotation Danio_rerio.Zv9.66.gtf file stored under the RNA-seq/annotation directory. On the top middle box you can specify the region you want your browser to zoom. Type: chr12:20,270,921-20,300,943

Alignment RNA-Seq

Can you identify the splice junctions from the BAM file?

Are the junctions annotated for CBY1 consistent with the annotation?

Are all annotated genes, from both RefSeq and Ensembl, expressed?

- samtools sort [bam_file_to_be_sorted] [prefix_of_sorted_bam_output_file] samtools index [sorted_bam_file]
- Once Tophat finishes running, sort the output BAM file and then index the sorted BAM file using the information above to guide you.

 Then load them onto IGV following the steps above.

Isoform Expression and Transcriptome Assembly

There are a number of tools that perform reconstruction of the transcriptome and for this workshop we are going to use Cufflinks. Cufflinks can do transcriptome assembly either ab initio or using a reference annotation. It also quantifies the isoform expression in FPKMs. A reminder from the presentation this morning that FPKM stands for 'Fragments Per Kilobase of exon per Million fragments mapped'.

Cufflinks has a number of parameters in order to perform transcriptome assembly and quantification. To view them all type:

```
1 cufflinks --help
```

We aim to reconstruct the transcriptome for both samples by using the Ensembl annotation both strictly and as a guide. In the first case Cufflinks will only report isoforms that are included in the annotation, while in the latter case it will report novel isoforms as well. The annotation from Ensembl of Danio rerio is stored under the directory annotation in a file called Danio_rerio.Zv9.66.gtf.

The general format of the cufflinks command is:

```
cufflinks [options] * <aligned_reads.(sam|bam)>
```

Where the input is the aligned reads (either in SAM or BAM format).

Some of available parameters of Cufflinks that we are going to use to run Cufflinks are listed below:

- -o Output directory
- -G Tells Cufflinks to use the supplied annotation strictly in order to estimate isoform annotation
- -b Instructs Cufflinks to run a bias detection and correction algorithm which can significantly improve accuracy of transcript abundance estimates. To do this Cufflinks requires a multi-fasta file with the genomic sequences against which we have aligned the reads
- -u Tells Cufflinks to do an initial estimation procedure to more accurately weight reads mapping to multiple locations in the genome (multi-hits).

--library-type See Tophat parameters

In the terminal type:

```
cufflinks -o cufflinks/ZV9_2cells_gff -G \
annotation/Danio_rerio.Zv9.66.gtf -b \
genome/Danio_rerio.Zv9.66.dna.fa -u --library-type fr-unstranded \
tophat/ZV9_2cells/accepted_hits.bam
```

Don't forget to change the output directory for the question section below. Otherwise your command will overwrite the results of the previous run.

Using the above command, which we used to pre-align the 2cells data, can you devise and run a command for the 6h data?

Take a look at the output directories that have been created. The results from Cufflinks are stored in 4 different files, see below.

Here's a short description of these files:

genes.fpkm_tracking Contains the estimated gene-level expression values.

skipped.gtf Contains loci skipped as a result of exceeding the maximum number of fragments.

transcripts.gtf This GTF file contains Cufflinks' assembled isoforms.

The complete documentation can be found at: http://cufflinks.cbcb.umd.edu/manual.html#cufflinks_output

Now in order to perform guided transcriptome assembly (transcriptome assembly that reports novel transcripts as well) we need to change the -G option of the previous command to -g instead. This tells Cufflinks to assemble the transcriptome using the supplied annotation as a guide, thus allowing for novel transcripts.

Performing the guided transcriptome analysis for the 2cells and 6h data sets would take 15-20min each. Therefore, we have pre-computed these for you and have the results available under subdirectories: cufflinks/ZV9_2cells and cufflinks/ZV9_6h.

Rather than running the commands for guided transcriptome assembly, which would take too much time, please have a think about the cufflinks command you would need to use to run in order to perform a guided transcriptome assembly for the 2cells dataset. Write your answer below:

- Go back to the IGV browser and load the file transcripts.gtf which is located in the subdirectory cufflinks/ZV9_2cells/. Rename the track into something meaningful. This file contains the transcripts that Cufflinks assembled based on the alignment of our reads onto the genome.
- In the search box type ENSDART00000082297 in order for the browser to zoom in to the gene of interest. Compare between the already annotated transcripts and the ones assembled by Cufflinks. Do you observe any difference?

Differential Expression

One of the stand-alone tools that perform differential expression analysis is Cuffdiff. We use this tool to compare between two conditions; for example different conditions could be control and disease, or wild-type and mutant, or various developmental stages. In our case we want to identify genes that are differentially expressed between two developmental stages; a 2cell embryo and 6h post fertilization.

The general format of the cuffdiff command is:

Where the input includes a transcripts.gtf file, which is an annotation file of the genome of interest, and the aligned reads (either in SAM or BAM format) for the conditions. Some of the Cufflinks options that we will use to run the program are:

-o output directory

- -L labels for the different conditions
- -T Tells Cuffdiff that the reads are from a time series experiment
- -b Same as for Cufflinks
- -u Same as for Cufflinks
- --library-type Same as for Cufflinks
- To run cufdiff type on the terminal:
 - cuffdiff -o cuffdiff/ -L ZV9_2cells,ZV9_6h -T -b \
 genome/Danio_rerio.Zv9.66.dna.fa -u --library-type fr-unstranded \
 annotation/Danio_rerio.Zv9.66.gtf \
 tophat/ZV9_2cells/accepted_hits.bam tophat/ZV9_6h/accepted_hits.bam
- In the command above we have assumed that the directory where you stored the results of Tophat for dataset 6h was named ZV9_6h. If this is not the case please change the previous command accordingly otherwise you will get an error.
 - We are interested in the differential expression at the gene level. The results are reported by Cuffdiff in the file cuffdiff/gene_exp.diff. Look at the first few lines of the file using the following command:
 - head -n 20 cuffdiff/gene_exp.diff

We would like to see which are the most significantly differentially expressed genes. Therefore we will sort the above file according to the q value (corrected p value for multiple testing). The result will be stored in a different file called gene_exp_qval.sorted.diff.

```
sort -t$'\t' -g -k 13 cuffdiff/gene_exp.diff > \
    cuffdiff/gene_exp_qval.sorted.diff
```

Look again at the first few lines of the sorted file by typing:

```
head -n 20 cuffdiff/gene_exp_qval.sorted.diff
```

Copy the Ensembl identifier of one of these genes. Now go back to the IGV browser and paste it in the search box. Look at the raw aligned data for the two datasets.

Do you see any difference in the gene coverage between the two conditions that would justify that this gene has been called as differentially expressed?

Note that the coverage on the Ensembl browser is based on raw reads and no normalisation has taken place contrary to the FPKM values.

Functional Annotation of Differentially Expressed Genes

After you have performed the differential expression analysis you are interested in identifying if there is any functionality enrichment for your differentially expressed genes. On your Desktop click:

Applications >> Internet >> Firefox Web Browser

And go to the following URL: http://david.abcc.ncifcrf.gov/ On the left side click on Functional Annotation. Then click on the Upload tab. Under the section Choose from File, click Choose File and navigate to the cuffdiff directory. Select the file called globalDiffExprs_Genes_qval.01_top100.tab. Under Step 2 select ENSEMBL_GENE_ID from the drop-down menu. Finally select Gene list and then press Submit List. Click on Gene Ontology and then click on the CHART button of the GOTERM_BP_ALL item.

Do these categories make sense given the samples weŠre studying?

Browse around DAVID website and check what other information are available.

de novo Assembly Introduction

Introduction

Some general introduction

Prepare the Environment

First make sure that you are in your home directory by typing:

1 cd

and making absolutely sure you're there by typing:

```
1 pwd
```

Now create sub-directories for this and the two other velvet practicals. All these directories will be made as sub-directories of a directory for the whole course called NGS. For this you can use the following commands:

```
mkdir -p NGS/velvet/{part1,part2,part3}
```

The -p tells mkdir (make directory) to make any parent directories if they don't exist. You could create the directories one-at-a-time by doing:

```
mkdir NGS
mkdir NGS/velvet
mkdir NGS/velvet/part1
mkdir NGS/velvet/part2
mkdir NGS/velvet/part3
```

After creating the directories, examine the structure and move into the directory ready for the first velvet exercise by typing:

```
1 ls -R NGS
2 cd NGS/velvet/part1
3 pwd
```

Downloading and Compiling Velvet

For the duration of this workshop, all the software you require has been set up for you already. This might not be the case when you return to Şreal lifeŤ. Many of the programs you will need, including velvet, are quite easy to set up, it might be instructive to try a couple.

Although you will be using the preinstalled version of velvet, it is useful to know how to compile velvet as some of the parameters you might like to control can only be set at compile time. You can find the latest version of velvet at:

```
http://www.ebi.ac.uk/~zerbino/velvet/
```

You could go to this URL and download the latest velvet version, or equivalently, you could type the following, which will download, unpack, inspect, compile and execute your locally compiled version of velvet:

```
cd ~/NGS/velvet/part1

pwd

cp ~/NGS/Data/velvet_1.2.07.tgz ./

tar xzf ~/NGS/Data/velvet_1.2.07.tgz

ls -R

cd velvet_1.2.07

make velveth velvetg

./velveth
```

Take a look at the executables you have created. They will be displayed as green by the command:

```
ls --color=always
```

The switch <code>--color</code>, offensively misspelled in American!, instructs that files be coloured according to their type. This is often the default. Here we are just being cautious. The <code>=always</code> is included as colouring is usually suppressed in scripts. If you run this exercise using the script provided, just <code>--color</code> would not be enough. <code>--color=always</code> insists on file colouring even from a script.

Have a look of the output the command produces and you will see that MAXKMERLENGTH=31 and CATEGORIES=2 parameters were passed into the compiler.

This indicates that the default compilation was set for De Bruijn graph k-mers of maximum size 31 and to allow a maximum of just 2 read categories. You can override these, and other, default configuration choices using command line parameters. Assume, you want to run velvet with a k-mer length of 41 using 3 categories, velvet needs to be recompiled to enable this functionality by typing:

```
make clean
make velveth velvetg MAXKMERLENGTH=41 CATEGORIES=3;
//velveth
```

Discuss with the persons next to you the following questions: What are the consequences of the parameters you have given make for velvet?

Why does Velvet use k-mer 31 and 2 categories as default?

Should you get better results by using a longer k-mer length?

velvet can also be used to process SOLID colour space data. To do this you need a further make parameter. With the following command clean away your last compilation and try the following parameters:

- make clean
- make MAXKMERLENGTH=41 CATEGORIES=3 color
- 3 ./velveth_de

| What effect would the following compil-time parameters have on velvet: OPENMP=Y |
|---|
| LONGSEQUENCES=Y |
| BIGASSEMBLY=Y |
| VBIGASSEMBLY=Y |
| SINGLE_COV_CAT=Y |

For a further description of velvet compile and runtime parameters please see the velvet Manual: https://github.com/dzerbino/velvet/wiki/Manual

Assembling Single-end Reads

The data you will examine is from Staphylococcus aureus USA300 which has a genome of around 3MB. The reads are Illumina and are unpaired, also known as single-end library. Even though you have carefully installed velvet in your own workspace, we will use a pre-installed version.

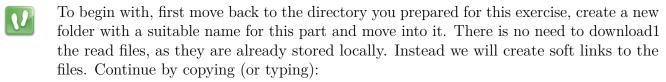

The data needed for this section can be obtained from the Sequence Read Archive (SRA). For the following example use the run data SRR022825 and SRR022823 from the SRA Sample SRS004748. The SRA experiment could be viewed by setting your browser to the URL:

http://www.ebi.ac.uk/ena/data/view/SRS004748

We have already downloaded the data files for you.

```
cd ~/NGS/velvet/part1
mkdir SRS004748
cd SRS004748

pwd
ln -s ~/NGS/Data/SRR022825.fastq.gz ./
ln -s ~/NGS/Data/SRR022823.fastq.gz ./
ls -1
```

You are ready to process your data with velvet, which is a compressed fastq file. Velvet has two main components:

velveth Used to construct, from raw read data, a dataset organised in the fashion expected by the second component, velvetg.

velvetg The core of velvet where the de Bruijn graph assembly is built and manipulated.

You can always get further information about the usage of both velvet programs by typing velvetg or velveth in your terminal.

Now run velveth for the reads in SRR022825.fastq.gz and SRR022823.fastq.gz using the following options:

- A de Bruijn graph k-mer of 25
- An output directory called run_25

```
velveth run_25 25 -fastq.gz -short SRR022825.fastq.gz SRR022823.fastq.gz
```

velveth talks to itself for a while and ends with some files in the output directory. Move into the output directory run_25 and take a look around at what velveth had done so far. The UNIX command less allows you to look at output files (press q for quit). Just in case you still need a hint:

```
cd run_25
ls -l
head Sequences
cat Log
```

What did you find in the folder run_25?

Describe the content of the two velveth output files?

What does the Log file store for you?

Now move one directory level up and run velvetg on your output directory, with the commands:

```
cd ../
time velvetg run_25
```

Move back into your results directory to examine the effects of velvetg:

```
cd run_22
ls -1
```

What extra files do you see in the folder run_25?

What do you suppose they might represent?

In the Log file in run_25, what is the N50?

Hopefully, we will have discussed what the N50 statistic is by this point. Broadly, it is the median (not average) of a sorted data set using the length of a set of sequences. Usually it is the length of the contig whose length, when added to the length of all longer contigs, makes a total greater that half the sum of the lengths of all contigs. Easy, but messy Ü a more formal definition can be found here:

http://www.broadinstitute.org/crd/wiki/index.php/N50

Backup the contigs.fa file and calculate the N50 (and the N25,N75) value with the command:

```
cp contigs.fa contigs.fa.0
```

gnx -min 100 -nx 25,50,75 contigs.fa

Does the value of N50 agree with the value stored in the Log file?

If not, why do you think this might be?

In order to improve our results, take a closer look at the standard options of velvetg by typing velvetg without parameters. For the moment focus on the two options

-cov_cutoff and -exp_cov. Clearly -cov_cutoff will allow you to exclude contigs for which the k-mer coverage is low, implying unacceptably poor quality. The -exp_cov switch is used to give velvetg an idea of the coverage to expect.

If the expected coverage of any contig is substantially in excess of the suggested expected value, maybe this would indicate a repeat. For further details of how to choose the parameters, go to 'Choice of a coverage cutoff':

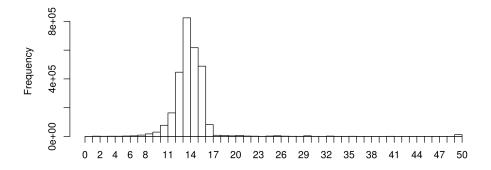

http://wiki.github.com/dzerbino/velvet/

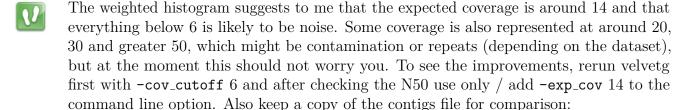

Briefly, the k-mer coverage (and much more information) for each contig is stored in the file stats.txt and can be used with R to visualize the coverage distribution. Take a look at the stats.txt file, start R, load and visualize the data using the following commands:

```
R --no-save --no-restore
library(plotrix)
data <- read.table("stats.txt", header=TRUE)
weighted.hist(data$short1_cov, data$lgth, breaks=0:50)
```

A weighted histogram is a better way of visualizing the coverage information, because of noise (lots of very short contigs). You can see an example output below:

```
cd ~/NGS/velvet/part1/SRS004748
time velvetg run_25 -cov_cutoff 6
3
```

```
# Make a copy of the run
cp run_25/contigs.fa run_25/contigs.fa.1

time velvetg run_25 -exp_cov 14
cp run_25/contigs.fa run_25/contigs.fa.2

time velvetg run_25 -cov_cutoff 6 -exp_cov 14
cp run_25/contigs.fa run_25/contigs.fa.3
```

What is the N50 with no parameter:

What is the N50 with -cov_cutoff 6:

What is the N50 with -exp_cov 14:

What is the N50 with -cov_cutoff 6 -exp_cov 14:

Did you notice a variation in the time velvetg took to run? If so, can you explain why that might be?

You were running velvetg with the <code>-exp_cov</code> and <code>-cov_cutoff</code> parameters. Now try to experiment using different cut-offs, expected parameters and also explore other settings (e.g. <code>-max_coverage</code>, <code>-max_branch_length</code>, <code>-unused_reads</code>, <code>-amos_file</code>, <code>-read_trkg</code> or see <code>velvetg</code> help menu).

Make some notes about the parameters you've played with and the results you obtained. Please also comment on the <code>-max_coverage</code> and <code>-max_branch_length</code> parameters.

In particular, look at the <code>-amos_file</code> parameter which instructs <code>velvetg</code> to create a version of the assembly that can be processed and viewed with a program called AMOS Hawkeye. Another program, called tablet, can also understand and display the AMOS file. For now, we will take a look at Hawkeye.

Run velvetg with just -cov_cutoff 6 but requesting an amos file:

velvetg run_25 -cov_cutoff 6 -amos_file yes

Now convert the AMOS message file velvet_asm.afg into an AMOS bank and view the assembly using AMOS Hawkeye.

```
bank-transact -c -b run_25/velvet_asm.bnk -m run_25/velvet_asm.afg hawkeye run_25/velvet_asm.bnk
```

Once the file has loaded in Hawkeye, select and display one of the longer contigs. Select the Contigs tab on the top of Hawkeye and take a closer look at the Contigs information. Note the lack of Read information and the one dimensional nature of the Contigs display. Close down Hawkeye when you have seen enough and delete the AMOS bank file.

```
1 rm -r run_25/velvet_asm.bnk
```

Now rerun velvetg adding the additional parameter -exp_cov 14 with no need to save any files as the AMOS file needs to be changed.

velvetg run_25 -cov_cutoff 6 -exp_cov 14 -amos_file yes

Again, convert the AMOS message file into an AMOS bank and view the assembly using Hawkeye or tablet:

- bank-transact -c -b run_25/velvet_asm.bnk -m run_25/velvet_asm.afg
- hawkeye run_25/velvet_asm.bnk

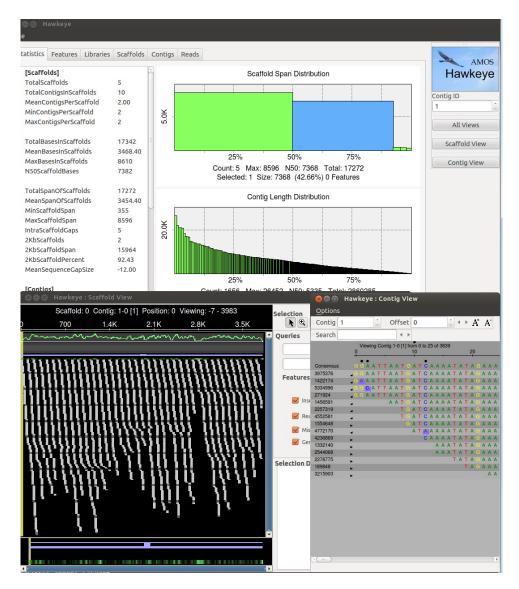

Figure 4: You should get a similar looking result with Hawkeye. If you are happy that you explored enough functionality, close down Hawkeye and continue with the exercise.

Why do you think there was read information only for the second use of Hawkeye and tablet?

You may have noticed velvetg took a little longer with -exp_cov 14 on. Does this make sense?

If you want to explore the behaviour of velvet even further, you could experiment with the following.

Reduce the sequence coverage by only choosing one input file for the assembly e.g. SRR022825.fastq.gz

Increase the sequence coverage by downloading further files from the same ENA sample SRS004748 http://www.ebi.ac.uk/ena/data/view/SRS004748.

How did the N50 change by a) reducing the coverage and b) increasing the coverage:

Simple Assembly Simulation

The data for this section is from Staphylococcus aureus MRSA252, a genome closely related to the genome that provided the short read data in the earlier sections of this exercise. The sequence data this time is the fully assembled genome. The genome size is therefore known exactly and is 2,902,619 bp.

In this exercise you will process the single whole genome sequence with velveth and velvetg, look at the output only and go no further. The main intent of processing this whole genome is to compute its N50 value. This must clearly be very close to the ideal N50 value for the short reads assembly and so aid evaluation of that assembly.

To begin, move back to the main directory for this exercise, make a sub-directory for the processing of this data and move into it. All in one go, this would be:

```
cd ~/NGS/velvet/part1/
mkdir MRSA252
cd MRSA252
```

Next, you need to download the genome sequence from http://www.ensemblgenomes.org/ which holds five new sites, for bacteria, protists, fungi, plants and invertebrate metazoa. You could browse for the data you require or use the file which we have downloaded for you. For the easier of these options, make and check a soft link to the local file and with the commands:

```
1 ln -s ~\
    /NGS/Data/s_aureus_mrsa252.EB1_s_aureus_mrsa252.dna.chromosome.Chromosome.fa.gz \
    ./
2 ls -l
```

Usually Velvet expects relatively short sequence entries and for this reason has a read limit of 32,767 bp per sequence entry. As the genome size is 2,902,619 bp - longer as the allowed limit and does not fit with the standard settings into velvet. But like the maximum k-mer size option, you can tell Velvet during compile time, using LONGSEQUENCES=Y, to expect longer input sequences than usual. I already prepared the executable which you can use by typing velveth_long and velvetg_long.

Now, run velveth_long, using the file you either just downloaded or created a soft link to as the input:

```
velveth_long run_25 25 -fasta.gz -long \
    s_aureus_mrsa252.EB1_s_aureus_mrsa252.dna.chromosome.Chromosome.fa.gz
velvetg_long run_25
```

What is the N50?

How does the N50 compare to the previous single end run (SRS004748)?

Does the total length differ from the input sequence length?

What happens when you rerun velvet with a different k-mer length?

Assembling Paired-end Reads

The data you will examine in this exercise is again from Staphylococcus aureus which has a genome of around 3MB. The reads are Illumina paired end with an insert size of 350 bp. The required data can be downloaded from the SRA. Specifically, the run data (SRR022852) from the SRA Sample SRS004748.

http://www.ebi.ac.uk/ena/data/view/SRS004748

The following exercise focuses on preparing the paired-end FASTQ files ready for velvet, using velvet in paired-end mode and comparing results with velvet's 'auto' option.

First move to the directory you made for this exercise and make a suitable named directory for the exercise:

- cd ~/NGS/velvet/part2
- 2 mkdir SRS004748
- 3 cd SRS004748

There is no need to download1 the read files, as they are already stored locally. You will simply create a soft link to this pre-downloaded data using the following commands:

ln -s ~/NGS/Data/SRR022852_?.fastq.gz ./

It would be interesting to monitor the way that the programs you will run utilize your computer's resources, particularly memory. A simple way to do this is to open a second terminal and in it type:

1 top

velvetg.

top is a program that continually monitors all the processes running on your computer, showing the resources used by each. Alternatively you could use a system monitor from your operating system as well. Leave this running and refer to it at intervals, especially when programs appear to be taking a long time, of just whenever your curiosity gets the better of you. You should find that as this practical progresses, memory usage will increase significantly, but hopefully not beyond the capacity of your workstation. Now, back to the first terminal, you are ready to run velveth and velvetg. The reads are -shortPaired this time and for the first run you should not use any parameters for

- From this point on, where it will be informative, time your runs. This is very easy to do, just prefix the command to run the program with the command time. This will cause UNIX to report how long the program took to complete its task.
- Set the two stages of velvet running, whilst you watch the memory usage as reported by top. time the velvetg stage. The commands to enter are:
 - velveth run_25 25 -fmtAuto -create_binary -shortPaired -separate \
 SRR022852_1.fastq.gz SRR022852_2.fastq.gz
 time velvetg run_25

What does -fmtAuto and -create_binary do? (see help menu)

Comment on the use of memory and CPU for velveth and velvetg?

How long did velvetg take?

Next, after saving your contigs.fa file from being overwritten, set the cut-off parameters that you investigated in the previous exercise and rerun velvetg. time and monitor the use of resources as previously. Start with -cov_cutoff 16 thus:

```
mv run_25/contigs.fa run_25/contigs.fa.0
time velvetg run_25 -cov_cutoff 16
```

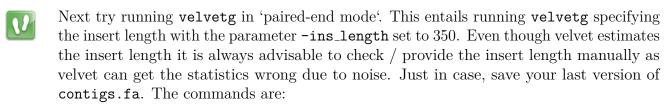

Up until now, velvetg has ignored the paired-end information. Now try running velvetg with both -cov_cutoff 16 and -exp_cov 26, but first save your contigs.fa file. By using -cov_cutoff and -exp_cov, velvetg tries to estimate the insert length, which you will see in the velvetg output. The command is, of course:

```
mv run_25/contigs.fa run_25/contigs.fa.1
time velvetg run_25 -cov_cutoff 16 -exp_cov 26
```

Comment on the time required, use of memory and CPU for velvetg?

Which insert length does Velvet estimate?

```
mv run_25/contigs.fa run_25/contigs.fa.2
time velvetg run_25 -cov_cutoff 16 -exp_cov 26 -ins_length 350
mv run_25/contigs.fa run_25/contigs.fa.3
```

How fast was this run?

Take a look into the Log file.

What is the N50 value for the $\tt velvetg$ runs using the switches: $\tt -cov_cutoff$ 16

-cov_cutoff 16 -exp_cov 26

-cov_cutoff 16 -exp_cov 26 -ins_length 350

Try giving the <code>-cov_cutoff</code> and/or <code>-exp_cov</code> parameters the value <code>auto</code> - the <code>velvetg</code> help output could show you how. The information Velvet prints during running includes information about the values used (coverage cut-off or insert length) when using the <code>auto</code> option.

Which coverage values does Velvet choose (hint: look at the output which velvet produces while running)?

How does the N50 value change?

Run gnx on all the contig.fa files you have generated in the course of this exercise. The command will be:

gnx -min 100 -nx 25,50,75 run_25/contigs.fa*

For which runs are there Ns in the contigs.fa file and why?

Comment on the number of contigs and total length generated for each run.

Similar to the single-end assembly you created previously, we can output a paired-end assembly as an AMOS message format file. This file can then be converted into an AMOS bank and viewed using AMOS Hawkeye.

```
time velvetg run_25 -cov_cutoff 16 -exp_cov 26 -ins_length 350 \
    -amos_file yes -read_trkg yes
time bank-transact -c -b run_25/velvet_asm.bnk -m \
    run_25/velvet_asm.afg
hawkeye run_25/velvet_asm.bnk
```

Looking at the scaffold view of a contig, comment on the proportion of happy mates to compressed mates.

What is the mean and standard deviation of the insert size report in the Libraries tab of Hawkeye?

Look at the actual distribution of insert sizes for this library. Can you explain where there is a difference between the mean and SD reported in those two places?

You can get AMOS to re-estimate the mean and SD of insert sizes. First, close Hawkeye and then run the following commands before reopening the AMOS bank to see what has changed.

- asmQC -b run_25/velvet_asm.bnk -scaff -recompute -update -numsd 2
- hawkeye run_25/velvet_asm.bnk

Looking at the scaffold view of a contig, comment on the proportion of happy mates to compressed mates.

What is the mean and standard deviation of the insert size report in the Libraries tab of Hawkeye?

Look at the actual distribution of insert sizes for this library. Does the mean and SD reported in each of those two places now match?

Data Quality

As discussed previously, fastq format files include quality assessment of each called base. As also mentioned earlier, velvet does not use this information directly. However, by taking into account the quality of the read data, it should be possible to both improve the efficiency (in terms of memory usage and runtime) and the quality of the output.

To investigate the effect of data quality, we will use the run data (SRR023408) from the SRA experiment SRX008042. The reads are Illumina paired end with an insert size of 92 bp

As ever, move up a directory to the main directory for the whole of this exercise and create and enter a new directory dedicated to this phase of the exercise. The commands are:

cd ~/NGS/velvet/part2

mkdir SRX008042
cd SRX008042

Create soft links to the read data files we downloaded for you from the SRA with the command:

1 ln -s ~/NGS/Data/SRR023408_?.fastq.gz ./

To look at the quality scores, you could use a tool called FastQC to process and present the scores in a compact manner of basic statistics. FastQC can be downloaded from:

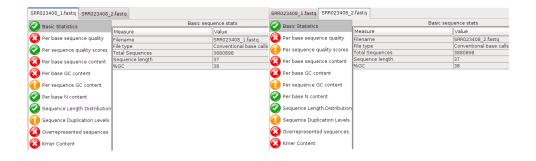

http://www.bioinformatics.bbsrc.ac.uk/projects/fastqc/

Where there are links to an excellent manual and an even more excellent youtube video. I hope to show you the video and recommend you keep the manual pages open whilst you are using FastQC in this exercise.

Start up FastQC Graphical User Interface (GUI) to examine your compressed fastq files by typing:

1 fastqc &

- The & sets FastQC running as a background job, thus freeing your terminal for further commands if required. FastQC emerges as a big blank window.
- Open both your compressed fastq files as was done in the video (Choose Open from the File pull down menu, browse to your files, select them both and click OK). Look at tabs for both files:

Are the quality scores the same for both files?

Which value varies?

Take a look at the Per base sequence quality for both files. Did you note that it is not good for either file?

At which positions would you cut the reads off?

Why does the quality deteriorate towards the end of the read?

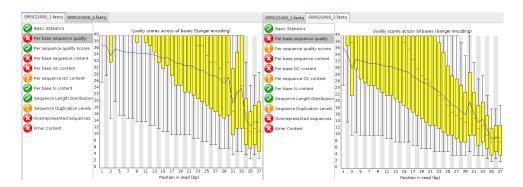

Does it make sense to trim the start?

Have a look at the other options that fastqc offers. Make good use of the Help to remind you of what you learned from the video. I suggest you open the Help window and keep it on your screen, open at the relevant page, as you browse through the fastqc possibilities.

Which other statistics could you use to support your trimming strategy?

Once you have decided how it might be sensible to trim your reads, close down fastqc by selecting Exit from the File pull down menu. Now apply the knife to your reads with fastx_trimmer from the FASTX-Toolkit. However, you will first need to decompress the FASTQ files. The usage of the tool can be found here:

http://hannonlab.cshl.edu/fastx_toolkit/commandline.html#fastx_trimmer_usage The suggestion (hopefully not far from your own thoughts?) is that you trim your reads as follows:

```
gunzip < SRR023408_1.fastq.gz > SRR023408_1.fastq
gunzip < SRR023408_2.fastq.gz > SRR023408_2.fastq
fastx_trimmer -Q 33 -f 4 -l 32 -i SRR023408_1.fastq -o \
SRR023408_trim1.fastq
fastx_trimmer -Q 33 -f 3 -l 29 -i SRR023408_2.fastq -o \
SRR023408_trim2.fastq
```

Now run velveth with a k-mer value of 21 for both the untrimmed and trimmed read files in -shortPaired mode. Separate the output of the two executions of velveth into suitably named directories, followed by velvetg. The commands would be:

What are the times for the two velvetg runs?

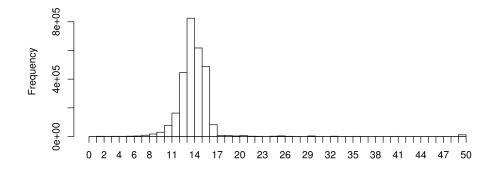

What N50 scores did you achieve?

What were the overall effects of trimming?

The evidence is that trimming improved the assembly. The thing to do surely, is to run velvetg with the <code>-cov_cutoff</code> and <code>-exp_cov</code>. In order to use <code>-cov_cutoff</code> and <code>-exp_cov</code> sensibly, you need to investigate with R, as you did in the previous exercise, what parameter values to use. To start up R and produce the weighted histograms, type:

```
R --no-save
library(plotrix)
data <- read.table("run_21/stats.txt", header=TRUE)
data2 <- read.table("run_21trim/stats.txt", header=TRUE)
x11()
par(mfrow=c(1,2))
weighted.hist(data$short1_cov, data$lgth, breaks=0:50)
weighted.hist(data2$short1_cov, data2$lgth, breaks=0:50)
```

One histogram suggests to me an expected coverage of around 13 with a coverage cut-off of around 7. The trimmed histogram instead suggests an expected coverage of around 9 with a coverage cut-off of around 5. If you disagree, feel free to try different settings, but first leave R before running velvetg:

```
q()
time velvetg run_21 -cov_cutoff 7 -exp_cov 13 -ins_length 92
time velvetg run_21trim -cov_cutoff 5 -exp_cov 9 -ins_length 92
```

How good does it look now?
Comment on:
Runtime

Memory

k-mer choice (Can you use kmer 31 for a read of length 30 bp?)

Does less data mean 'worse' results?

How would a smaller/larger Kmer size behave?

Compare the results, produced during the last exercises, with each other:

| SRR022852 | SRR023408 | SRR023408.trimmed |
|-----------|-----------|-----------------------|
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | SRR022852 | SRR022852 SRR023408 |

What would you consider as the 'best' assembly?

If you found a candidate, why do you consider it as 'best' assembly?

Assembling Long (454) Read

The data you will examine in this exercise is again from Staphylococcus aureus which has a genome of around 3MB. The reads are 454 single end.

The required data can be downloaded from the SRA. Specifically, the run data (SRR000892,SRR000893) from the SRA Experiment SRX000181.

http://www.ebi.ac.uk/ena/data/view/SRX000181

The following exercise focuses on processing 454 long reads with velvet and how this differs compared to short reads.

First move to the directory you made for this exercise and make a suitable named directory for the exercise before downloading the read files:

- cd ~/NGS/velvet/part3
- 2 mkdir SRX000181
- 3 cd SRX000181

The downloaded files can be used directly in velvet. To let velvet know that these fastq files are long reads, you pass in the parameter -long by using the commands:

```
1  ln -s ~/NGS/Data/SRR000892.fastq.gz
2  ln -s ~/NGS/Data/SRR000893.fastq.gz
3  velveth run_25 25 -create_binary -fastq.gz -long *.fastq.gz
4  time velvetg run_25
```

Take a look at the stats.txt file. Which columns are used compared to short reads and why?

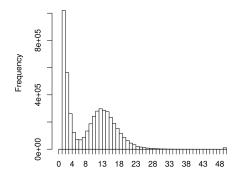

Which N50 do you get?

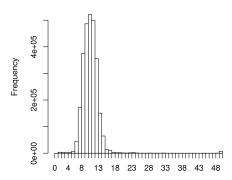

How long did the velvetg run take?

The right thing to do is to run velvetg setting the cut-offs. But for long reads there is an option called <code>-long_cov_cutoff</code> to filter them independently because of the difference in usage in velvet. To investigate with R, as you did in the previous exercises, start up R and produce the weighted histogram using the column <code>long_cov</code> by typing:

```
R --no-save
library(plotrix)
data <- read.table("run_25/stats.txt", header=TRUE)
x11()
weighted.hist(data$long_cov, data$lgth, breaks=0:50)
```

For me the histogram suggests to me to choose a coverage cut-off of around 9 with an expected coverage of about 19. If you disagree, feel free to try different settings, but first leave R before running velvetg with the coverage parameters typing:

```
q()
1
2
   cp run_25/contigs.fa run_25/contigs.fa.0
3
4
5
   time velvetg run_25 -long_cov_cutoff 9
   cp run_25/contigs.fa run_25/contigs.fa.1
6
7
   time velvetg run_25 -long_cov_cutoff 9 -exp_cov 19
8
   cp run_25/contigs.fa run_25/contigs.fa.2
10
   gnx -min 100 -nx 25,50,75 run_25/contigs.fa.*
11
```

What is the N50 and runtime using:
-long_cov_cutoff 9

-long_cov_cutoff 9 -exp_cov 19

other runs?

Which other parameters could improve the assembly quality for long reads?

What do you think about assembling 454 reads with Velvet?

Assembling Mixed Insert Length Libraries

Like the previous examples, the data you will examine in this exercise is again from Staphylococcus aureus which still has a genome of around 3MB. The reads are Illumina paired end with an insert size of 170 bp and 350 bp.

You already downloaded the required reads from the SRA in previous exercises. Specifically, the run data (SRR022863, SRR022852) from the SRA Study SRP001086.

http://www.ebi.ac.uk/ena/data/view/SRP001086

The following exercise focuses on handing two insert length libraries with velvet and the changes you have to look out for.

First move to the directory you made for this exercise, make a suitable named directory for the exercise and check if all the files are in place:

- cd ~/NGS/velvet/part3
- 2 mkdir SRP001086

```
3 cd SRP001086
4 ln -s ~/NGS/Data/SRR022863_?.fastq.gz ./
5 ln -s ~/NGS/Data/SRR022852_?.fastq.gz ./
```

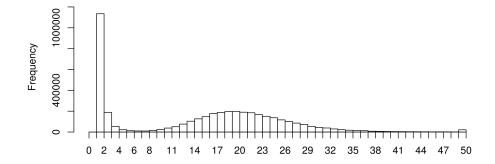

Now run velveth and velvetg using the appropriate command line options by typing:

```
time velveth run_25 25 -fmtAuto -create_binary -shortPaired -separate \
    SRR022863_1.fastq.gz SRR022863_1.fastq.gz -shortPaired2 -separate \
    SRR022852_1.fastq.gz SRR022852_2.fastq.gz

time velvetg run_25
```

The right thing to do is to run velvetg setting the cut-offs. To investigate with R, as you did in the previous exercises, start up R and produce the weighted histogram using the columns short1_cov and short2_cov by typing:

```
R --no-save
library(plotrix)
data <- read.table("run_25/stats.txt", header=TRUE)
weighted.hist(data$short1_cov+data$short2_cov, data$lgth, breaks=0:70)
```

For me the histogram suggests to me to choose a coverage cut-off of around 20 with an expected coverage of about 36. If you disagree, feel free to try different settings, but first leave R before running velvetg with the coverage parameters typing:

```
q()
cp run_25/contigs.fa run_25/contigs.fa.0

time velvetg run_25 -cov_cutoff 20
cp run_25/contigs.fa run_25/contigs.fa.1

time velvetg run_25 -cov_cutoff 20 -exp_cov 36
cp run_25/contigs.fa run_25/contigs.fa.2
```

What N50 did you get?

How did the runtime/results compare to one paired-end library runs?

How many different libraries would you be able to run with this velvet version?

Would you be able to add a single-end library as well with this velvet version?

Find and download a different insert length library ¹ from the study SRP001086 and recompile velvet to allow the use of three insert length libraries. Maybe you could use the library you trimmed during previous exercises. You should be able to find these files here: /NGS/velvet/part2/SRX008042/SRR023408_trim?.fastq. If you don't still have these files, you can find a copy of them here: /NGS/Data/SRR023408_trim?.fastq Use the fresh compiled Velvet version with the three (two provided and one downloaded library) to assemble the genome.

Does the extra library make any difference?

How does the overall coverage change?

Any other comments?

^aPaired insert lengths can be found on the NCBI SRA page in the library section (Nominal length) e.g. http://www.ncbi.nlm.nih.gov/sra?term=SRR022866

Hybrid Assembly

Like the previous examples, the data you will examine in this exercise is again from Staphylococcus aureus which has a genome of around 3MB. The reads are 454 single end and Illumina paired end with an insert size of 170 bp. You already downloaded the required reads from the SRA in previous exercises. Specifically, the run data (SRR022863, SRR000892, SRR000893) from the SRA experiments SRX007709 and SRX000181.

The following exercise focuses on handing 454 long reads and paired-end reads with velvet and the differences in setting parameters.

First move to the directory you made for this exercise, make a suitable named directory for the exercise and check if all the three files are in place:

- cd ~/NGS/velvet/part3
- 2 mkdir SRR000892-SRR022863
- 3 cd SRR000892-SRR022863
- 4 ln -s ~/NGS/Data/SRR00089[2-3].fastq.gz ./
- 1 ln -s ~/NGS/Data/SRR022863_?.fastq.gz ./

The following command will run for a LONG time. This indicated the amount of calculations being preformed by Velvet to reach a conclusion. To wait for velvet to finish would exceed the time available in this workshop, but it is up to you to either let it run over night or kill the process by using the key combination CTRL+c.

```
velveth run_25 25 -fmtAuto -create_binary -long \
SRR00089?.fastq.gz -shortPaired -separate \
SRR022863_1.fastq.gz SRR022863_2.fastq.gz
time velvetg run_25
```

If you have decided to continue, we already inspected the weighted histograms for the short and long read library separately, you can reuse this for the cut-off values:

time velvetg run_25 -cov_cutoff 7 -long_cov_cutoff 9

What are your conclusions using velvet in an hybrid assembly?
